Corporate Cash Management Digital Transformation Case Study

Summary

This self-directed Business Analysis case study prepared by Vutomi Faith Khosa looks at a documented problem in corporate banking: businesses with accounts at several banks cannot see their total cash in one place. I analysed the stakeholders and current state, defined and prioritised requirements, mapped the process, and built an Excel and Power BI prototype using invented sample data. The prototype shows balances across accounts, monthly cash in and out, and cash runway. I tested it with six checks and documented its limitations.

1. Stakeholder Analysis (CATWOE)

Customers

Finance managers and treasury staff at the bank's business clients, such as retail companies that keep separate accounts for store sales, online sales and supplier payments.

Actors

The bank's digital and IT team who build and maintain the portal, and the relationship managers who support clients as they use it.

Transformation

Transform a process where finance teams log into several bank portals and manually add up balances in spreadsheets into a single consolidated view of cash across all linked accounts.

Weltanschauung

Finance teams lose time and make weaker decisions when their money is spread across disconnected systems. A single, current view helps a business plan with confidence, and a bank that provides it is more likely to keep that client.

Owner
Bank executives, such as the head of corporate or transaction banking, who approve investment in the portal.

Environmental Constraints

- Banking regulation and data security requirements
- Difficulty connecting to other banks' systems and data formats
- The cost of building and maintaining those connections
- Finance teams who are used to their current manual process

2. Current State Analysis

A business with accounts across several banks, such as a retailer with separate accounts for store sales, online sales and supplier payments, currently logs into each bank's portal and compiles the figures in a spreadsheet to see its overall cash position. Industry research from banking technology providers describes similar problems, and there are four main ones.

Fragmentation
There is no real-time view of total cash across accounts. The manual snapshot is often out of date by the time it is finished.

Forecasting Difficulty
Predicting future cash flow is largely manual and prone to error.

Inefficient Payments
Paying suppliers from different accounts means switching between systems, which increases the risk of delay or mistakes.

Slow Onboarding
Opening new business accounts and completing identity and compliance checks (KYC) is often paper-heavy and slow.

3. Future State Vision

The proposed future state is a single digital portal offered by the bank. It consolidates balances and transactions from all of a client's linked accounts into one dashboard. It shows basic financial indicators, including net cash flow and cash runway, and lets the client make payments from any linked account through one interface. New business clients can complete onboarding and identity verification digitally. Every payment requires secure authentication.

4. Gap Analysis

Gap 1
Current state: balances are scattered across several bank portals.
Future state: one consolidated dashboard.
Bridge: link the accounts and combine their balance data.

Gap 2
Current state: forecasting is manual and error prone.
Future state: automatic cash flow indicators.
Bridge: calculate net cash flow and cash runway from transaction history.

Gap 3
Current state: payments go through separate systems.
Future state: one payment interface.
Bridge: centralised payment initiation with secure authentication.

Gap 4
Current state: onboarding is slow and paper-based.
Future state: digital onboarding.
Bridge: an online identity verification and KYC workflow.

5. Requirements

Requirement 1: Consolidated Balance View
Functional: As a finance manager, I want to see all my company's account balances in one dashboard, so that I do not have to log into separate banking portals to understand our cash position.
Non-functional: Balance data should refresh at least once daily, or in real time where the bank's systems allow it.
Priority: Must Have

Requirement 2: Cash Flow Indicators
Functional: As a finance manager, I want to see net cash flow and estimated cash runway, so that I can plan payments and spending with more confidence.
Non-functional: The indicators should update automatically when new transaction data is loaded.
Priority: Should Have

Requirement 3: Centralised Payment Initiation
Functional: As a finance manager, I want to pay suppliers from any linked account through one interface, so that I do not have to switch between banking systems.
Non-functional: Every payment must require secure authentication before it is processed.
Priority: Must Have

Requirement 4: Digital Onboarding
Functional: As a new business client, I want to complete account setup and identity verification online, so that I can start banking faster than with paper forms.
Non-functional: The target completion time is to be confirmed through operational testing.
Priority: Could Have

Priorities use the MoSCoW method (Must have, Should have, Could have, Won't have). Requirements 1 and 3 are Must Have because the project fails without them. Requirements 2 and 4 add value once that foundation works.

6. Process Model

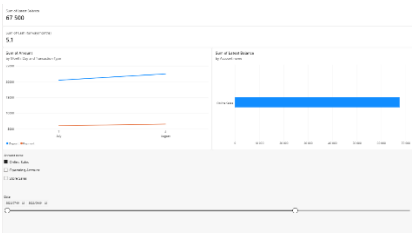

The process model shows the journey from login to the end of the session. There is one main decision point, which is whether the user wants to make a payment.

1. The finance manager logs in with their credentials and authenticates securely.
2. The system retrieves the latest balances and transactions from all linked bank accounts.

3. The dashboard displays consolidated balances, recent transactions and cash flow indicators.
4. Decision point: does the user want to make a payment?

- If yes, the user selects the account, enters the payment details and authenticates. The payment is processed, a confirmation is shown, and a confirmation email is sent.
- If no, the user continues reviewing the dashboard.

5. The session ends, and the data refreshes before the next login.

(Same at the one next to summary)

7. Prototype

A prototype was built in Excel and Power BI to demonstrate part of the proposed solution. It uses invented sample data for three mock accounts across three banks, covering July to September 2026.

Excel holds the transactions (opening balances, deposits and payments), each account's latest balance, a monthly summary of cash in, cash out and net cash flow, and a cash runway calculation. Cash runway is the total of the latest balances divided by the average monthly cash out.

The Power BI dashboard shows total balance across all accounts, cash runway in months, balance by account, monthly cash in versus cash out, and filters by account and date.

[Insert your dashboard screenshot here]

The prototype does not connect to any real bank. It does not process payments or onboarding, and it does not model transfers between accounts. Cash runway is a simple estimate, and real forecasting would need more sophisticated methods. The prototype is a proof of concept for the consolidated view idea and would need further development before real use.

8. Change Management

Introducing this portal means change for several groups.

Finance Teams at Client Businesses
They need training and clear instructions to move from checking each bank separately to using one consolidated dashboard.

Relationship Managers
They need to understand the portal well enough to support clients confidently through the transition.

The Bank's IT Team
They need to manage the technical integration with other banks' systems and test it thoroughly before launch.

Communication
The change should be explained clearly to clients and staff, to reduce confusion and resistance.

Implementation
The safest approach is a phased rollout. The portal is first piloted with a small group of clients, feedback is collected, problems are fixed, and the rollout is then expanded. This keeps mistakes cheap to fix and builds confidence before wider release.

The main purpose of change management is to make sure people are prepared for the new process and that the technology is adopted successfully.

9. Initial Testing

The prototype was tested using six scenarios to check that the main functions worked as expected.

Test 1: Data loads from every account
Expected: all three accounts appear, and the dataset contains 36 transactions.
Result: Pass

Test 2: Total balance equals the sum of the latest balances
Expected: 280,500, which is 192,500 plus 67,500 plus 20,500.
Result: Pass

Test 3: Net cash flow equals cash in minus cash out for each month
Expected: July 44,000, August 84,500 and September 52,000.
Result: Pass

Test 4: Cash runway matches a manual calculation
Expected: 280,500 divided by the average monthly cash out of 55,000, which is about 5.1 months.
Result: Pass

Test 5: Filters update the visuals
Expected: selecting an account changes the bar chart and the total balance card, and the date filter changes the line chart.
Result: Pass. The balance visuals show latest balances, so they respond to the account filter but not the date filter. This is by design.

Test 6: Dashboard stays readable
Expected: nothing overlaps, labels are legible and no errors appear.
Result: Pass

During building, the total balance card first showed each account separately, and the bar chart first counted rows instead of adding balances. In both cases the field setup was corrected so the values were summed, and the results were then retested. This tested the dashboard's calculations against manual checks.

10. Conclusion

This case study examined a documented problem in corporate banking: businesses with accounts across several banks, including retailers, lack a single current view of their cash. The proposed portal consolidates balances, shows basic cash flow indicators, centralises payments and digitises onboarding. An Excel and Power BI prototype demonstrates the core

consolidated view idea using sample data. The project shows how a Business Analyst moves from identifying a problem to analysing the current state, defining and prioritising requirements, designing a future state and testing a working proof of concept.
